- Challenges
- Conclusions

### **Problem Statement**

The problem statement is to predict the price range of mobile phones based on the features available (price range indicating how high the price is). Here is the description of target classes:

- 0 Low cost Phones
- 1 Medium cost phones
- 2 High cost phones
- 3 Very High cost phones

This will basically help companies to estimate price of mobiles to give tough competition to other mobile manufacturer.

Also, it will be useful for consumers to verify that they are paying best price for a mobile.

### **Data Summary**

- We have records of 2000 mobile phones with 20 columns/features.
- We have perfectly balanced dataset with 500 observations for each class.
- Each column represents the feature of the mobile.
- Interestingly, we had zero null values.

### **Data Overview**

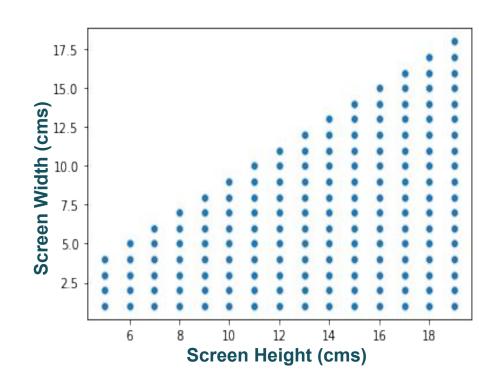

- Battery\_power Total energy a battery can store in one time measured in mAh
- Blue Has bluetooth or not
- Clock\_speed speed at which microprocessor executes instructions
- Dual\_sim Has dual sim support or not
- Fc Front Camera megapixels
- Four\_g Has 4G or not
- Int\_memory Internal Memory in Gigabytes
- M\_dep Mobile Depth in cm
- Mobile\_wt Weight of mobile phone
- N\_cores Number of cores of processor
- Pc Primary Camera megapixels
- Px\_height Pixel Resolution Height
- Px\_width Pixel Resolution Width
- Ram Random Access Memory in MegaBytes
- Sc\_h Screen Height of mobile in cm
- Sc\_w Screen Width of mobile in cm
- Talk\_time longest time that a single battery charge will last
- Three\_g Has 3G or not
- Touch\_screen Has touch screen or not
- Wifi Has wifi or not
- Price\_range This is the target variable with value of 0(low cost), 1(medium cost), 2(high cost) and 3(very high cost).

# **Handling Discrepancies**

In the data we observed that in 9% of rows the value for columns 'sc\_w' (screen width) is 0, which is not possible in real life.

As we can see in the plot, for each value of 'sc\_h' there are multiple values of 'sc\_w', so to handle zero values, we replaced them with mean of all available values 'sc\_w' for all values of 'sc\_h'.

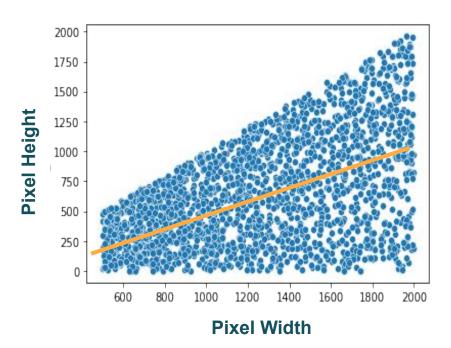

# **Handling Discrepancies**

There are also discrepancies in 'Px\_height' column.

To handle those discrepancies we replaced those values by using linear regression.

# **Feature Engineering**

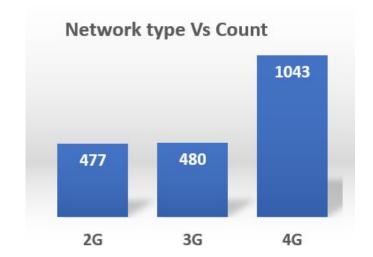

- Generally the screen size of the phone is expressed in Inches.
- We have columns 'sc\_h' and 'sc\_w' out of which we have created a new feature 'Screen\_size' which is diagonal length of the screen.

# **Feature Engineering**

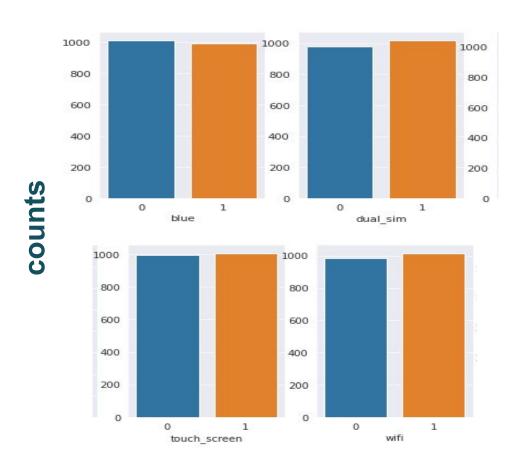

3G	0	,T	3G	1	T.	3G	0	,T	3G	1	,T
4G	0	"T	4G	0	J.	4G	1	JT	4G	1	Ţ
Neither 3G Nor 4G			3G but not 4G			4G but not 3G			Both 3G and 4G		
<b>Price Category</b>	Cour	it	<b>Price Category</b>	Count		Price Categ	gory 💌 Cour	ıt	<b>Price Category</b>	▼ Count	
Low	127		Low	114		<b>Grand Tota</b>	Î		Low	259	
Medium	122		Medium	116					Medium	262	
High	113		High	140					High	247	
Very High	115		Very High	110					Very High	275	
<b>Grand Total</b>	477	3/6 9/8	<b>Grand Total</b>	480	100				<b>Grand Total</b>	1043	

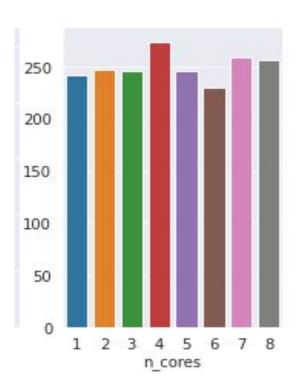

- We observed that if a phone supports 4G, it by default has 3G as well. So we don't really need two columns for this.
- We created a single column 'network' by the addition of 3G and 4G. Where:
- 0 2G, 1 3G, 2 4G.

# **Categorical Analysis**

# Collinearity

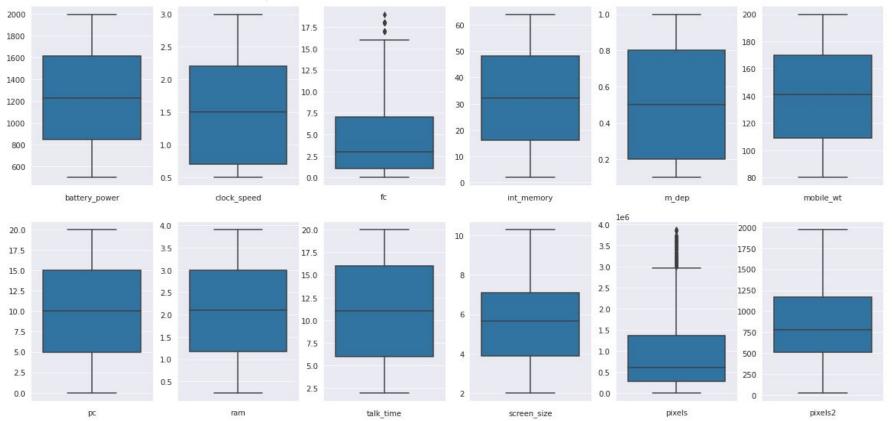

We created a new column 'Pixels' by taking the product of 'px\_height' and 'px\_width'.

# **Outlier Analysis in continuous features**

There were few outliers in 'pixels' column, so to handle outliers we replaced the values of 'Pixels' column with the square root.

# **Predictive Modelling**

### **Hyperparameter Tuning - Grid Search - Cross Validation**

We compared 6 classifiers and evaluated them based on overall accuracy & class based accuracy as well.

- Decision Trees
- Random Forest
- Ada Boost
- Gradient Boosting
- XGBoost
- Logistic Regression

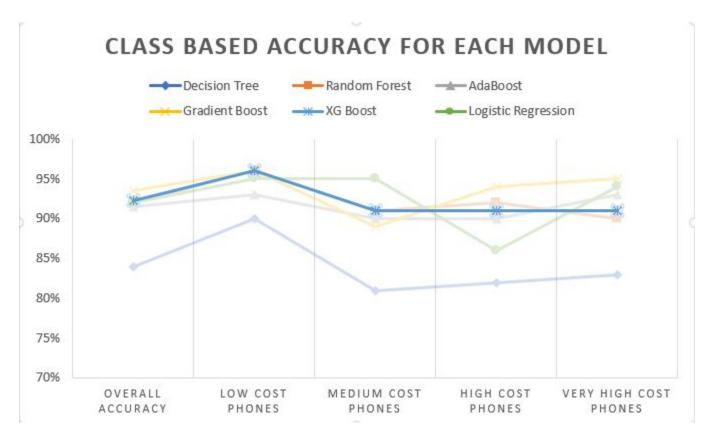

# **Comparison of Models**

#### CLASS BASED ACCURACY FOR EACH MODEL

# **Comparison of Models**

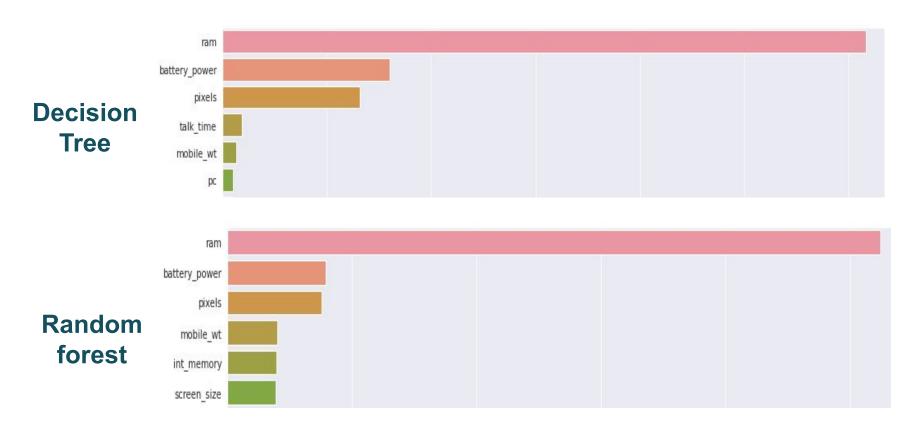

XG Boost is the best performing model on the given dataset

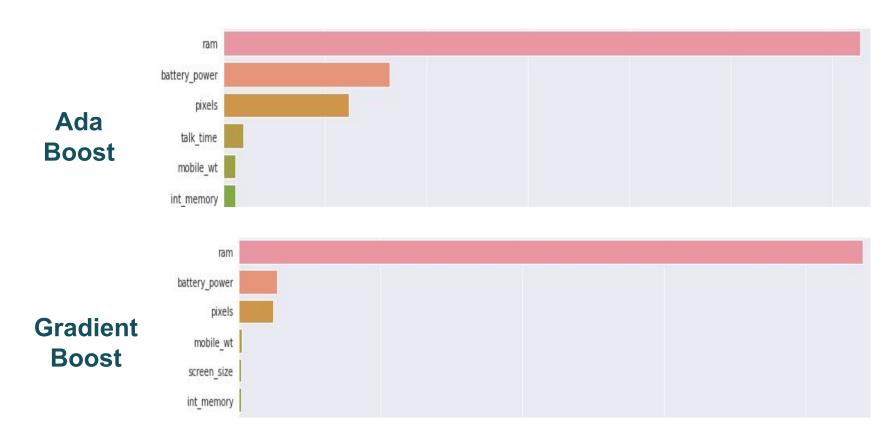

# **Feature Importance**

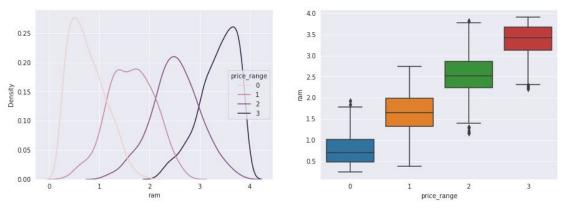

# **Feature Importance Contd..**

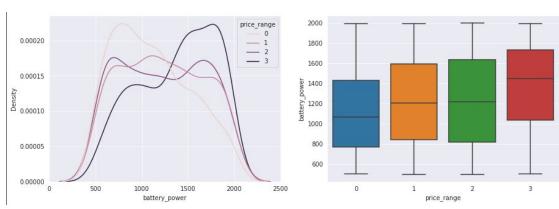

# Feature Importance Contd..

- RAM and battery power are two most important features for the models.
- RAM and
   Battery power
   show the most
   variation along
   the different
   price ranges.

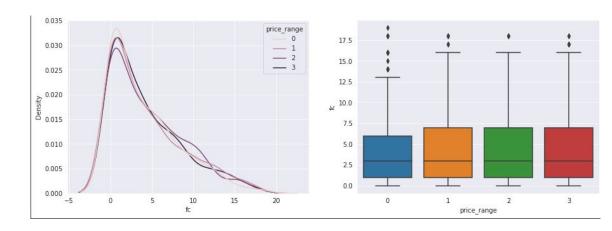

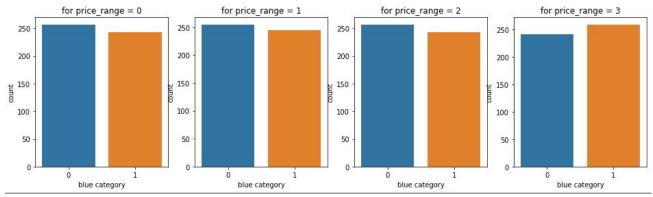

# Feature Importance Contd..

- Apart from selected important features any feature doesn't show variation along the different price ranges.
- Here is example of front camera and bluetooth.

# Challenges

- We performed "Hypothesis driven EDA" based on domain, but unluckily most of our hypothesis got rejected by our data.
- Most of the models are not able to get good accuracy for each class of target variable.
- We hit a ceiling at 94% accuracy using a single model.

### Conclusion

- Gradient Boost, Random forest and ADABoost Models are also giving us good overall accuracy but they didn't perform well on Individual classes.
- Out of all the model we have tried XG Boost is performing well on Overall as well as Individual classes.
- Ram, Battery power, Mobile weight, Screen size and pixels are key features in predicting the mobile price range.
- Most of the mis-classifications were encountered between Medium range phones and high range phones. To counter that we can train a specific model for these two classes and can reclassify the cases when base model predicts the result as Medium range or High range.
